## On the road again <br> Higher driver death rate is a downside of economic recovery

The risk of dying in a crash in a latemodel vehicle has gone up slightly, as a stronger economy has led drivers to take to the road more often and in more dangerous ways. Meanwhile, a new study predicts traffic deaths will fall only slightly over the coming years, given current expectations for the economy.

The overall rate of driver deaths for 2014 models is 30 per million registered vehicle years, up from 28 for 2011 models (see Status Report, Jan. 29, 2015, at iihs. org). The death rate for individual vehicles varies widely, from 0 for 11 vehicles to 104 per million registered vehicle years for the Hyundai Accent, a minicar.
The last time IIHS calculated driver death rates, the overall rate had fallen by more than a third over three years. Researchers found that the drop was driven largely by improved vehicle designs and safety technology. Such improvements have continued, but the new

## Economic recovery brings more driving and also riskier types of driving. The result is more crash deaths.

results show that, by themselves, they won't be enough to eliminate traffic deaths.
"Vehicles continue to improve, performing better and better in crash tests," says David Zuby, IIHS executive vice president and chief research officer. "The latest driver death rates show there is a limit to how much these changes can accomplish without other kinds of efforts."

The new driver death rates are based on deaths that occurred during 2012-15. The increase in the overall driver death rate for 2014 models is likely connected to the increased number of fatalities toward the end of that period.

## Falling unemployment, rising crash deaths

Road deaths have been trending downward since the early 1970s, with an especially large dip beginning in 2008. However, that changed in 2015, with deaths increasing 7 percent over the previous year. Preliminary data indicate the toll increased in 2016 as well. In the new study, Charles Farmer, IIHS vice president for research and statistical services, looked at what economic forecasts can tell us about traffic fatalities over the coming years.
An increase in traffic deaths is a predictable downside to an improving economy. As unemployment falls, both vehicle miles traveled and crash deaths increase (see Status Report, Dec. 10, 2015). In a stronger economy, people tend to drive more. Riskier, discretionary driving - for example, going out to dinner or traveling for vacation - is affected by economic fluctuations even more than day-to-day commuting. Economic conditions also affect how fast people drive.
To estimate how the annual death toll might change in the coming years, Farmer designed a statistical model based on the connection between traffic deaths and unemployment since 1990. The model also includes calendar year, thereby (" page 6)

# Death rates by make and model 

## Driver deaths per million registered vehicle years

These rates are for 2014 models, but results are included for earlier model years as far back as 2011 if the vehicle wasn't substantially redesigned during that time. A change in electronic stability control from not available or optional to standard is treated as a redesign. Exposure is the number of registered vehicle years. A registered vehicle year is one vehicle registered for one year.
Rates are adjusted for driver age and gender.
Information on deaths is from the National Highway Traffic Safety Administration's Fatality Analysis Reporting System. Data on vehicle registrations come from IHS Automotive.

# Summer road trips mean more traffic deaths 

The summer and early fall are the most dangerous times of year on the nation's roads, an updated IIHS analysis confirms. Fatalities also are higher on weekends and in the late afternoon and evenings, while Independence Day and New Year's Day have the highest average toll of any single date.

The trends reflect the fact that Americans drive the most miles during the warm summer months. Weekends and certain holidays with increased alcohol consumption also see spikes in deaths.

## An analysis of fatal crashes between 1998

 and 2014 found that summer and early fall are the most dangerous times of the year. Weekends are deadlier than weekdays, and the highest number of deaths occur between 3 p.m. and 7 p.m.To find out when crashes are most likely to occur, IIHS researchers examined federal fatal crash data from 1998 to 2014. They chose that period because each day of the week occurred the same number of times, and every date except Feb. 29 fell on each day of the week at least twice. The study
confirms many of the trends identified in an earlier IIHS analysis of traffic deaths during 1986-2002 (see Status Report, July 3, 2004, at iihs.org).
"Roadway deaths have declined since our original study, but the pattern of deaths is unchanged," says Charles Farmer, IIHS vice president for research and statistical services. "The riskiest times remain risky."
Annual traffic deaths fell during the new study period, with most of the drop occurring between 2007 and 2010. The number of fatalities averaged 106 per day during the 17-year period.
As in the earlier analysis, weekends were deadlier than weekdays. There were an average of 139 deaths on Saturdays, compared with 89 on Tuesdays. The highest number of deaths occurred between 3 p.m. and $7 \mathrm{p} . \mathrm{m}$. and the lowest between $3 \mathrm{a} . \mathrm{m}$. and 6 a.m.

July and August were the deadliest months, with an average daily toll of 116 . They were followed by June, October and September.

January and February had the lowest daily tolls and, not coincidentally, the lowest number of vehicle miles traveled.

Among January days, New Year's Day was an exception, with an average of 135 deaths. That's the second-highest after July 4 , which had an average of 141 deaths.
The two holidays also were among the highest-fatality days in the previous study. Many communities conduct impaireddriving enforcement initiatives at those times of years, and the average number of fatalities has dropped on both days. However, Independence Day saw more progress, with fatalities falling 13 percent. In contrast, New Year's Day fatalities fell only 5 percent.

Pedestrian deaths, which comprised 12 percent of all traffic deaths during the study period, were generally highest in late November and early December, when days are getting shorter. Jan. 1 was the worst single day for pedestrian deaths.
Motorcyclist deaths accounted for 10 percent of fatalities. July 4 had the highest number of motorcyclist fatalities, and the other dates in the top 10 also were in warm-weather months.
For a copy of "Temporal factors in motor vehicle crashes - 10 years later" by $R$. Weast, email publications@iihs.org.
(«from page 2) accounting for safer vehicle designs and other highway safety improvements that have taken hold over time.

Farmer found that a decline in the unemployment rate from 6 percent to 5 percent is associated with a 2 percent increase in vehicle miles traveled. That jump in exposure leads to an equivalent 2 percent jump in fatalities. However, after accounting for the change in miles traveled, the decline in the unemployment rate is associated with an additional 2 percent increase in road deaths. In other words, only half of the effect of an improved economy on traffic deaths is due to increased driving.

Given the U.S. Bureau of Labor Statistics' forecast of a 1.7 percent annual reduction in unemployment from 2014 to 2024, he predicts that the recent increase in deaths will
have peaked in 2016 and estimates there will be approximately 34,400 traffic deaths in 2024 , compared with 35,092 in 2015.
If unemployment doesn't change as predicted but remains steady at the 2016 rate of 4.9 percent, there will be 33,600 traffic deaths, Farmer estimates. In either case, the projected number of crash deaths for 2024 is still higher than the 32,744 deaths seen in 2014.
The recent surge in crash avoidance technologies, along with the development of autonomous vehicles that in theory could eliminate all crashes, has the potential to bring down crash rates. However, it will take decades before such technologies are present in all new vehicles. Vehicles with varying degrees of automation will be sharing the road with conventional vehicles for some time (see Status Report special issue:
autonomous vehicles, Nov. 10, 2016).
"Improvements in vehicle technology are important, but we also need to address old problems such as speeding and driving while impaired," Farmer points out.

## Tiny vehicles, high death rates

As in the past, the driver death rates show that the smallest vehicles are the most dangerous ones. Among the 10 vehicles with the highest rates, five are minicars and three are small cars. These vehicles don't protect occupants as well as larger ones, so their presence at the top of the "worst" list isn't surprising.

Among vehicle categories, 4-door minicars have the highest overall death rate of 87, while 4-wheel-drive large luxury SUVs have the lowest with 6.

Deaths by month
Average number of deaths per day, 1998-2014

Deaths by day of the week
Average number of deaths per day, 1998-2014

Despite the increase in the overall rate, the worst vehicles actually saw some improvement. The 2014 Hyundai Accent's death rate of 104 compares with 120 for the 2011 Accent. The worst vehicle among the 2011 models was the Kia Rio with a rate of 149 . The 2014 Rio's death rate is 102. Both models were redesigned in 2012, and their lower death rates may reflect the better crash-test performance of the newer designs.

IIHS has been publishing death rates per registered vehicle year by make and model since 1989 (see Status Report, Nov. 25, 1989). The rates include only driver deaths because all vehicles on the road
have drivers, while not all of them have passengers or the same number of passengers. Fatality counts are taken from the federal Fatality Analysis Reporting System, and registration data are from IHS Automotive. The calculated rates are adjusted for driver age and gender.

Although the numbers reflect 2014 models, data from earlier models as far back as 2011 are included if the vehicles weren't substantially redesigned before 2014. Including older, equivalent vehicles increases the exposure and thus the reliability of the results. To be included, a vehicle must have had at least 100,000 registered vehicle years of exposure during 2012-15 or at least 20 deaths.

@IIHS_autosafety

IIHS is an independent, nonprofit scientific and educational organization dedicated to reducing the losses — deaths, injuries and property damage - from motor vehicle crashes.

HLDI shares and supports this mission through scientific studies of insurance data representing the human and economic losses resulting from the ownership and operation of different types of vehicles and by publishing insurance loss results by vehicle make and model.

Both organizations are wholly supported by the following auto insurers and funding associations:
